Abstract

The resources and services offered by cloud computing platforms have been opening new alternatives of expansion to several research areas. The cloud computing platform applications to the educative area have been creating interest in different educative organizations. This thesis proposes the use of the Amazon EC2 cloud computing platform to build networking laboratories for the computational and networking educative areas. Within this paper, several options are evaluated in order to fulfill this objective. The final proposed design introduces a practical scenario for networking laboratories. Future enhancements of the final design are proposed.

1 Introduction

The infrastructure of real networking and information technology laboratories is supported on advanced equipment, and therefore getting an accessible budget for such purposes could be a difficult task. With the advent of virtual machines technologies, new possibilities are being created for the purpose of establishing new learning methodologies that will contribute to a more deep rooted education in this subject.

The use of this technology for educative reasons has its limitations and disadvantages. Some of those reasons are based on lack of familiarity by students, the lack of resources that support this technology, as well as other obstacles that make difficult the final implementation of this educational tool.

With the widespread use of Cloud Computing and the use of a reliable Lab Manager on this environment, the limitation of resources could be easily solved as Cloud Computing environment can offer countless different machine images each one with different resources.

Regarding investment issues, we need to visualize each scenario in order to recognize the impact of the cloud computing platform. The physical platform is based on software and hardware equipment for each student; this implies that each student needs to interact physically with a real scenario; therefore there will be an investment on computers, switches, routers and software licensing for each student. Furthermore, the space requirements of a networking laboratory need to be considered as an important aspect,

because this kind of laboratory requires an assigned space for multiple students at the same time. As an example, for the implementation of a simple network environment of two interconnected nodes through a router, it would be necessary to invest in two PCs and one router for each student; which could employ investment on an onerous platform to acquire and maintain, also the space requirements could limit the quantity of students inside the laboratory. In the same way, a physical laboratory can be used only by one group of students on a specified schedule, so the availability of the lab would be limited by the time assigned to each group. Furthermore, the hardware components of a physical laboratory have a limited lifespan and resource availability, because the technology advance fast, the resources needs to be increased with the time and the equipment would fail, so it is important to update periodically the hardware platform of the laboratories.

On the other hand, the virtualization of the laboratories using a group of servers to accomplish the function of a physical platform relieves some part of the issues. Nevertheless, the virtualization scheme implies the investment on a high performance computing server farm, which could include high memory, processing power and space requirements that should support several Virtual Machines launched at time. Moreover, resources availability is tied to the funds invested in the server infrastructure. In the same way, this type of platform requires the periodical renew of the hardware components, since these equipments would be affected by the aging, and also dependent to future enhancements to expand the resources as the requirements go up with the time. These variables could lead to an expensive platform investment that might not be reachable for every educational entity.

In contrast, the cloud computing platform could accomplish the objectives of a physical scenario, but reducing or eliminating the investment for new hardware, software licenses, space requirements and power considerations. The cost impact of this platform could be minimal, because this platform is based on a “pay per use” scheme. Every resource will pay a quota per hour, which means that we would be paying dynamically for the resources used every hour. This is an important factor to consider, because we will not need to invest on a local expensive server farm nor individual hardware and software, since we will be investing on a dynamic payment option. Moreover, this new platform could be implemented by both, low resources educational entity and the big wealthy educational institution, because it offers a shared resources environment that is available through the internet; also, the low resources educational institutions will have the chance to work in the same way as the big wealthy educational institutions, being capable to expand their laboratories resources to the cloud computing environment, maintaining a limited and dynamic budget.

As a result, given the vast opportunities that the Cloud Computing platform (CCP) offers to the educative environment, the creation of virtual laboratories are proposed using the virtual machines technologies based on the CCP, in conjunction with tools of remote administration, for the implementation of a modern and efficient educative system. Our goal in this Thesis is to evaluate the viability of designing virtual networking labs (VNL) in a CCP.

2 Literature Review

There are many works in the area that are related with the creations of laboratories on a virtual environment. These works can be categorized in three main areas.

2.1 Virtual Laboratories

On the virtual laboratories area, many researchers [1] [2] [3] [4] have developed different studies that are focused on the analysis and implementation of a virtual laboratory infrastructure for both distance learning and local campus students.

Bullers Jr, W. I. and Stephen, B (2006), conducted a qualitative research about the use of a virtual platform (based on VMware workstation software) and the teaching experience in network administration, information security and database administration courses using this virtual platform. Similarly, Border, C. (2007) introduced a virtual laboratory solution for the RIT networking and System Administration classes named Remote Laboratory Emulation System (RLES). This solution was based on a combination of different software technologies of remote management and the use of the VMware Workstation virtual platform. His goal was to develop a remote laboratory in which the students could deploy several services in order to construct a functional virtual network. In the same way, but in a broad topic, a virtual laboratory are tried to be developed; however, it is focused on a different platform.

Correspondingly, Stackpole, B. (2008), analyzed the current path of laboratories virtualization process emphasizing the actual cost of a physical infrastructure environment. Within this paper, the virtual platform implementation is compared to the physical infrastructure implementation, and the laboratories performance as well as the student satisfaction was evaluated to measure the level of achievement of this virtual solution. Moreover, Stackpole, B. et al. (2008) conducted a qualitative analysis of the VMware based laboratory platform that are used in the RIT, in which they review the technology and variables that are related with this platform. However, both papers evaluate a virtual infrastructure that is based on a physical virtualization platform, but this Thesis evaluates a different virtualization approach that is related to Cloud Computing environment.

2.2 Cloud Computing

The cloud computing area has been increasing its research scope, because this area has been offering a high computational resources at a reduced cost, motivating the study of new developments in the educational area. Many researchers [5, 6, 7, 8 and 9] have done studies related to the cloud computing platform.

Deelman, E. et al. (2008), conducted a cost research in the cloud computing area, where they were analyzing the economic impact of this platform by using an astronomical application. They concluded that the cloud computing environment (like Amazon EC2) offers a cost-effective solution for intensive CPU applications. Furthermore, Hazelhurst, S (2008) studied the scientific uses of the Cloud Computing Amazon EC2 commercial

environment, in which they concluded that this platform provides a cost-effective to the scientific areas. These papers are focused on the cloud computing solutions for scientific and astronomical areas, but this Thesis is focused on an educational objective.

3 Problem statement

Seeing the early stages of the networking educational platforms, the development of the laboratories has been focused on physical infrastructure facilities that implied investment on equipments and software that could represent additional costs to educational institutions. For this situation local virtualization technologies were implemented in order to reduce the impact of future investments; this type of technology has appeared to expand the educational platforms, which are related to informational systems. Platforms have appeared that offer virtualization resources in the cloud, which proposes a challenge to the development of the educational platforms as regards networking laboratories. In order to develop virtual laboratories on the CCP, it is necessary to define processes and schemes for the construction of those laboratories, which present a challenge for the proposed goal. Besides that, the CCP showed several limitations of connectivity and handling of the virtual devices that could be used to establish the educational platforms. Another problem could be that the platform might turn out to be not friendly to the user.

4 Significance and Benefits

- There would be a reduction in the operation and maintenance of a local physical or virtual infrastructure for educational purposes, since these processes might be implemented inside of a centralized cloud computing platform.
- The educational entities would not have to invest in the acquisition of equipment nor hardware update needed for the implementation of an educational platform.
- There would be an optimization of the resources usages, because the cloud computing platform is supported over a shared resources environment.

5 Methodology

For the methodology used in the evaluation of the viability of designing virtual networking labs in a Cloud computing environment it was tried an implementation in multiple phases.

A network is a group of interconnected points that allow multiples nodes to exchange information through different communications media or gateways. In this case, a network may allow several hosts to intercommunicate among themselves, through a predefined communication path; in contrast, a single node alone could not be able to exchange information with other endpoints, which definitely does not comply with the definition of a network. A virtual network on the cloud should allow testing from physical to the application layer of the TCP/IP Protocol Stack; in the same way, it should allow simulating a basic routing environment.

For this Thesis the primary goal was the simulation of a real networking environment, in which it could replicate two or more machines that were connected together, being isolated from other VM on the network in order to be able to test networking operations and exchange of packets between them. This platform must allow the arrangement of several machines with multiple network interfaces to reproduce an adequate routing environment. It was a required feature, because it was used a VM as a router, and a router should be capable of interconnect several network, so this VM should had more than one routing interface in order to act as a real router.

In the first phase of the Thesis, Amazon EC2 Cloud Computing platform and VMLogix Lab Manager are used to set a Remote Virtual Laboratory. Multiple test scenarios were implemented in this laboratory to test our proposition. These scenarios were focused on the implementation of basic network communications, basic routing labs and client-server networking labs.

At the second phase, in which the evaluation of the platform features and options were done, design of different scenarios was the main goal. This phase was focused on an ample analysis of the platform that could allow covering all the areas, related to the use of the infrastructure. Subsequently, an exhaustively implementation of the tests in each scenario was done. These scenarios evaluate the ability of the platform to permit routing protocols to run.

On the first scenario, two virtual machines are being configured as routers. The main purpose of this scenario was to develop a virtual tunnel between those VMs and execute a static routing, as well as the RIP protocol to test the dynamic routing features of this platform. With this scenario there was developed a virtual network around these VMs; therefore exchange of packets was done directly among the VMs.

On the second scenario, four virtual machines are configured; two machines as desktop OS and the other two are used as routers. The idea behind this scenario was to expand the network from just two routers of the first scenario; consequently it could interconnect two host machines using those routers. Dynamic routing protocols were used in this scenario to advertise the networks behind each router. This configuration complies with the concept of a network, because it could exchange information around these virtual paths.

The resources of VMLogix as well as the resources and tools of Amazon EC2 to generate virtual machines and OS images were used in the design of the test scenarios. The resources provided by VMLogix are User management, Images Manipulation, Networking configuration (Security Groups between VMs) and virtual machines control. Those resources are used from Amazon EC2, because VMLogix manages the resources of Amazon with a structured way and focused on an educational platform.

For the implementation of each test scenarios, there was used the Linux distribution named Vyatta, which offer several features and options that could be used to construct a routing environment. Moreover, it could use several OS images that include Cent OS or

Windows 2003 OS Virtual Machines, which are part of the networking environment in each test scenario. Those images (as well as other Linux images like Ubuntu and Vyatta) are the only options available for doing a network configuration, and the reason is that Amazon only have license for Windows 2003 Images but does not have for other types of windows OS at this time.

Finally, in the last phase, the results obtained in the previous phase were analyzed in order to verify if the Virtual platform could be used for the pursued objective.

6 Test Environment

The idea to create a virtual networking laboratory base on the use of resources in the cloud was developed searching for a reduction on the actual cost of implementing a physical networking laboratory. To consolidate this idea it was necessary to create a work agenda in order to reach our objectives. That agenda consist on several steps, which are broken down as follow:

6.1 Platform description

Amazon Elastic Computing 2 (Amazon EC2) it is a CCP, which offers computational resources services through the internet. This platform requires an account in Amazon.com; this account needs to have assigned funds to allow access to the processing resources in the cloud.

Once the account is created, the link <http://aws.amazon.com/ec2> is used to access the main page of Amazon EC2 CCP.

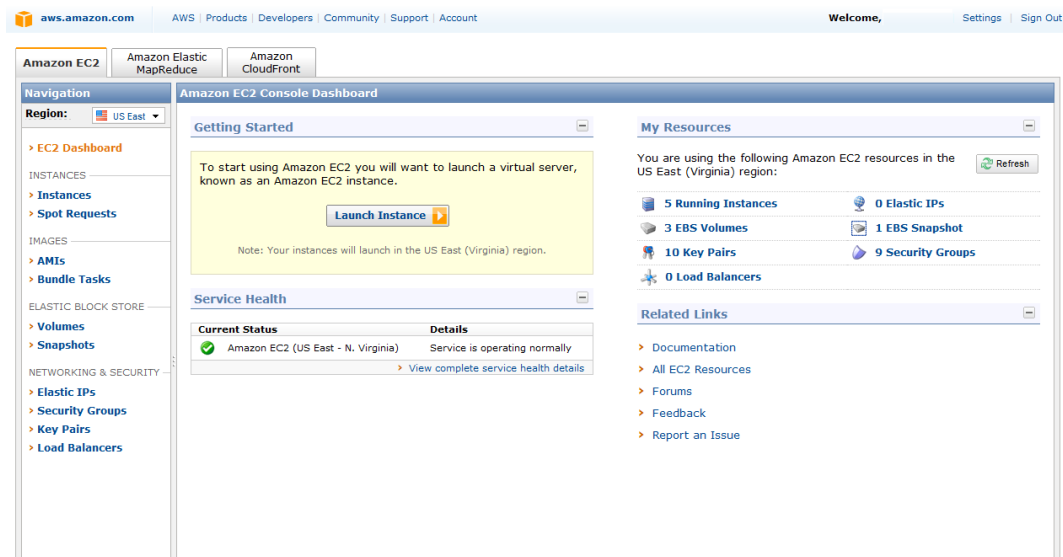

Fig. 1 - Amazon EC2 Initial Page

Amazon EC2 allows creating instances and manipulating the images of operative systems that have already been created. Also, Amazon EC2 has tools that could be used to capture OS images, which allow storing the data for future uses or for data recovering in case of failures.

At the same time, Amazon EC2 allows having private storage spaces through Amazon S3 (Amazon Storage 3). These private storage spaces can be used to store specific data that belongs to the deployed OS images. In order to have this storage available in Amazon EC2 it is necessary to create virtual disks through the EBS (Elastic Book Store), which is

an option that is managed by the EC2 administration console. Once it has established the access to the private storage spaces, there are many applications that can benefit from this option. Among these applications can be found databases storage usage, user storage configuration, backup storage systems, and other applications that need a robust storage platform could also be benefit because in other circumstances would be expensive to maintain.

Amazon EC2 and Amazon S3 are managed by VMLogix Cloud Edition; this is a virtual manager for remote laboratories. It uses the same resources provided by Amazon EC2 and Amazon S3 to take the necessary steps that allow the user easy access to these resources. In this case, this software could be used to create a teaching platform in the cloud that can be used to impart laboratory classes related to the areas of computation and information technology. In this particular case this platform could be used as a support for the networking laboratories.

VMLogix is a fundamental piece for this Thesis, since it provides the necessary tools that are needed to establish an effective platform in the educational field. This software allows adequate access to the resources of Amazon EC2 CCP, as well as an organized and less complicated way to use this platform, which is favorable to the educational goals.

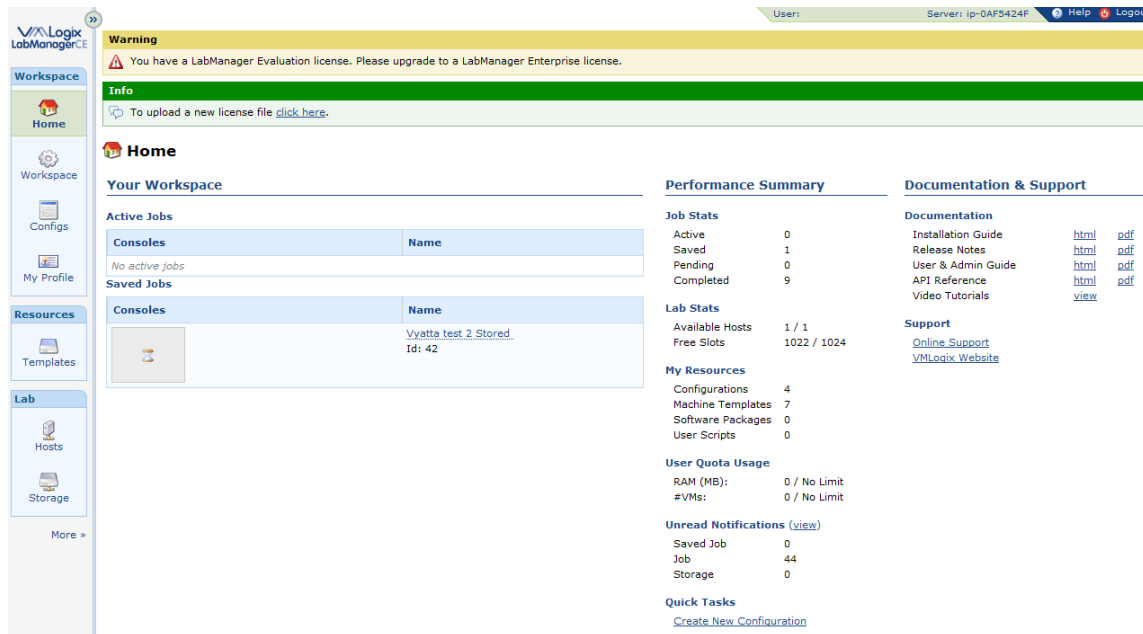

Fig. 2 - VMLogix Cloud Edition initial page

In order to have access to this software an appropriate license is needed, which is provided by the VMLogix organization. In this case was used a software license for educational purposes.

6.2 Platform capability Tests

For the evaluation of the networking capabilities of this platform a focus was taken on the configuration details of virtual machines. The objective of this evaluation is to verify if this platform allows the possibility of creating virtual networking configurations, in which it could simulate real life networks. Since real life networks allow point-to-point and multipoint connections between real life machines it should be able to do the same with this new platform.

Fig. 3 - New Configuration on VMLogix

VMLogix offers multiple VM configurations, which can be defined by the OS to use, as well as the details of software configuration that these VMs would use. One option to emphasize is the one related to Security groups that each VM belongs to when they are launched by VMLogix.

 **EC2 Security Group Template: Default EC2 Security Group Template** 

EC2 Security Group Template Information

EC2 Security Group Template Name:

Default EC2 Security Group Template

Description:

Allows RDP, SSH, VNC on Port 3389, 22, 5900 from everywhere

Allowed Connections

Connection Method	Protocol	From Port	To Port	Source IP
RDP	tcp	3389	3389	0.0.0.0/0
VNC	tcp	5900	5900	0.0.0.0/0
SSH	tcp	22	22	0.0.0.0/0

Fig. 4 - VMLogix Security Configuration

According to the test ran, these groups of security are related with external access regulations of the VMs. These groups define the ports that are going to give access to

users for the VM control from a remote location in the internet. By the way, the machines created within the same group have total access among them through the transport protocols TCP, UDP and ICMP.

Job Defaults

Job Deployment Lease Time: Hour(s)
 Default timeout for a new job.

Job Deployment Max Lease Time: Day(s)
 Maximum lease timeout for a new job. Specifying '0' would mean 'No Max Timeout'.

Action on Job Deployment Lease Time:
 What should LabManager do if job gets timed-out.

Job Deployment Lease Notification Time: Hour(s)
 Default time for a job lease notification.

Saved Job Lease Time: Week(s)
 Default timeout for a saved job.

Saved Job Lease Notification Time: Day(s)
 Default time for saved job lease notification.

Ask 'description' while deploying with defaults: ☐ Ask the user for a 'description'
 Whether the user should be asked to enter a 'description' while deploying a configuration with defaults.

RAM threshold for load balancing: %
 RAM threshold value in percentage to perform load balancing across hosts.

Slot threshold for load balancing: %
 Slot threshold value in percentage to perform load balancing across hosts.

'Sync Machines' Timeout: minutes *
 Default timeout for the 'Synchronize Machines' operation.

Default RAM for Role: MB *
 Default RAM for roles when default RAM role policy is 'Server Default'.

Default RAM Policy for Role: ☒ Template Default ☐ Server Default
 Default RAM for a role will be picked by default from the option selected above.

IPZone: ☐ Enabled
 Default IP Zone Selection.

Default Network Policy:
 Choose network policy for IP Zones. For policy with 1:1 NAT, public IP pool must be configured on server to use

Auto Release When Guest OS Not Active: ☒ Enabled
 When selected, roles resources will be automatically released once that role's guest machine is not active for sometime i.e. VM is powered off in case of VMagents

Wait time for auto release after Guest OS is not active: seconds *
 Number of seconds LabManager should wait before releasing role resources, if guest OS is not active

Add 'Change Host Name' Operation: ☐

Fig. 5 - VMLogix Administration Options – Job Defaults

VMLogix have several administrative options that focus in the control of the definitions of the virtual configurations. Between the modifiable options there are the configuration run time, the amount of memory assigned to each VM, synchronization preferences, and other options related with the access of the VMs from external networks. It should be noted that it has been verified that some of the options do not execute the way they should; this is because this version of VMLogix was adapted from a version that is not

related to CCP.

The screenshot shows the 'Remote Access Settings' page in the VMLogix administration interface. It contains several configuration sections: 'Remote LAN Access' with 'Enable' selected; 'Remote WAN Access' with 'Disable' selected; 'WAN Repeater IP' and 'WAN Repeater Port' (set to 5901) fields; 'Amazon EC2 Managed Hosts' with 'Enable Guest Operating System Remote Options' checked; 'Guest Operating System Remote Options' with multiple checkboxes for RDP, SSH, LabManager VNC, and NX Remote Proxy; and 'Global NX Remote Proxy Settings' with fields for hostname/IP and port (22), and 'Enable encryption of NX Remote Proxy traffic' checked.

Fig. 6 – VMLogix Administration Options – Remote Access Settings

In reference to the access configuration, VMLogix offers different access mediums to the VM, which consist in access through SSH, RDP and VNC. To achieve connectivity to VM, multiple plug-in of access can be used, as well as direct access through third party software (like VNCviewer, PUTTY and Microsoft Remote Desktop).

6.3 Platform's limitations and issues for development

The screenshot shows the 'Deploy Job: Basic Machine Network' page. It includes a 'Basic Information' section with fields for 'Job Run Name' (filled with 'Basic Machine Network'), 'Description', and 'User Notes'. There is also a 'Job Deployment Lease Time' section with a dropdown menu set to 'DEFAULT' and a note about automatic undeployment. An 'Advanced Options' link is at the bottom left.

Fig. 7 – VMLogix Configuration Deployment

To run connectivity tests between VMs a configuration was created with two VMs, by which are established the platform limitations.

Machine Role: Machine-A

Select Machine Template:

Microsoft Windows Server 2k3 with Auth Ser with

Choose the Machine Template to install for this role. You can also request a machine with specific amount of RAM and other options.

Deploy On Machine:

Machine-B

Fig. 10 - VM #1 and VM #2 information

Fig. 11 – Win2k3 VM, RDP Console

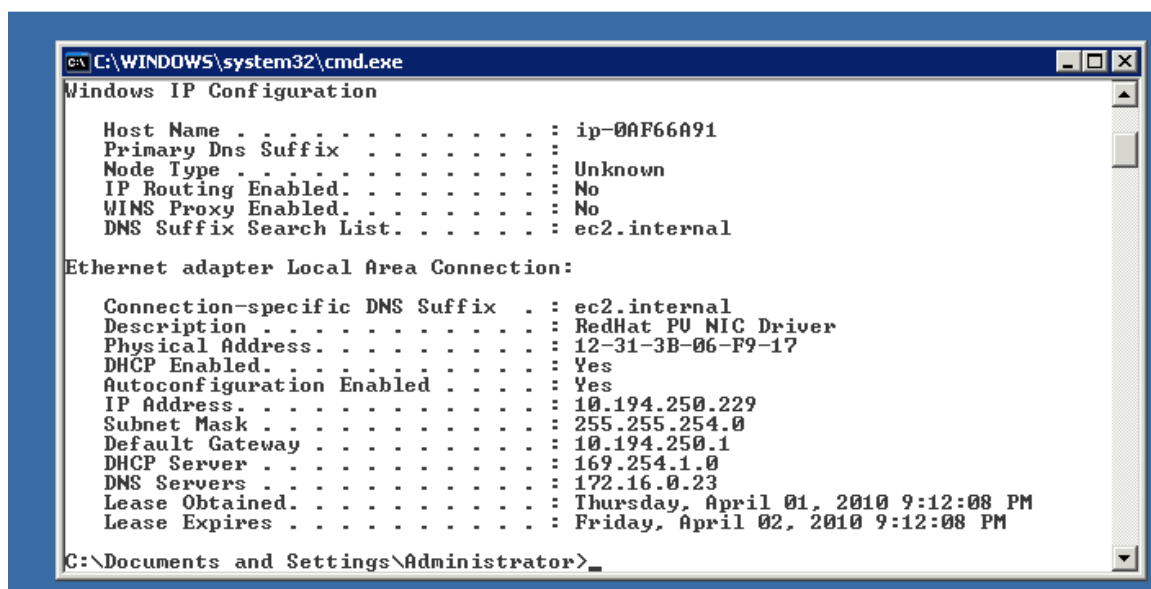

Fig. 12 – ipconfig command results – VM #1

According to this data the assigned IPs to each VM are determined by the usage of a DHCP server, therefore it can be assumed that it is not possible to assign specific fixed addressed to these VMs.

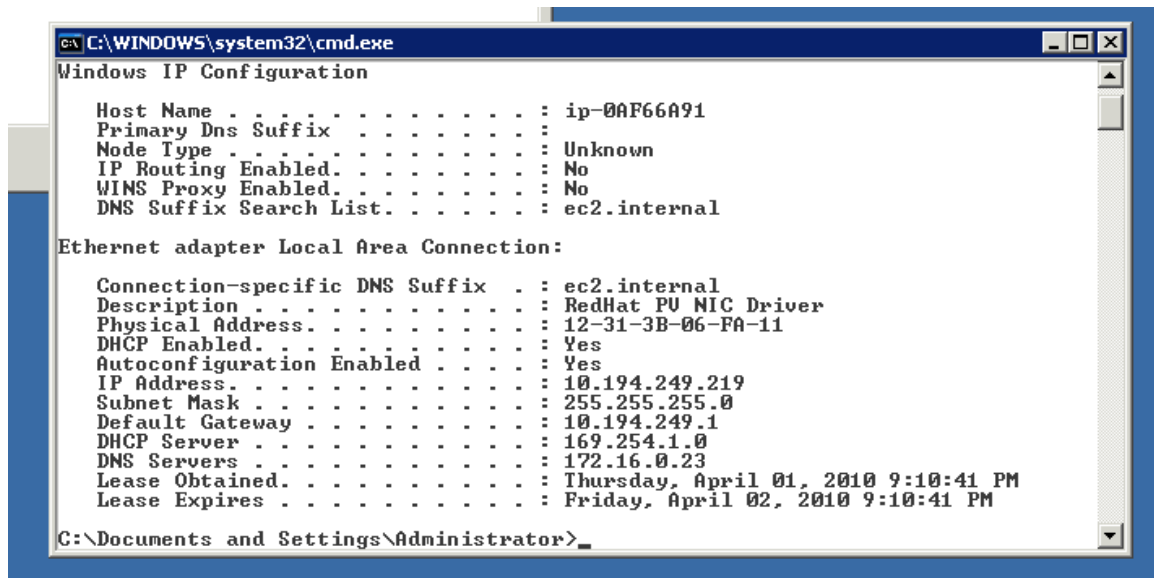

Fig. 13 - ipconfig command output - VM #2

To each VM different subnets are assigned, as well as different gateways. This creates a link between both VM through virtual routers or virtual nodes, for which it was no access to establish routing tests.

The CCP of Amazon, which is managed through VMLogix, does not allow the specific manipulation of each VM, because the control of these machines is done through the IP protocol. In the same way, the true control of the VMs is done internally by the Amazon EC2 platform.

Group Name:

LM-Job-1997-LMEC2SecurityGroup-0-11ea9ca505519948f818889e831d1fc8

Description:

LabManager Security Group

Allowed Connections:

Connection Method	Protocol	From Port ▲	To Port	Source (IP or group)	Actions

All	tcp	0	65535	LM-Job-1997-LMEC2SecurityGroup-0-11ea9ca505519948f818889e831d1fc8 group	Remove
All	udp	0	65535	LM-Job-1997-LMEC2SecurityGroup-0-11ea9ca505519948f818889e831d1fc8 group	Remove
RDP	tcp	3389	3389	0.0.0.0/0	Remove
Custom...	--				Save

Fig. 14 - Amazon EC2's Security Configuration Tab

Through the Amazon EC2 console it was able to evaluate the access configuration assigned to the launched VMs. By the use of this console it could modify the access restrictions of the VMs, and also it can be noted that the permission assignment can be done to the TCP, UDP and ICMP transport protocols only.

6.4 Platform's alternatives

Seeing the previously exposed limitations it could be stated that the CCP platform of Amazon does not allow changing the configurations related to the link of each VM through the layer 2 nor the layer 3 of the TCP/IP protocol stack. So it is necessary to develop alternatives that could allow passing over those limitations.

In order to be able to create point to point network configurations between nodes, data encapsulation could be used. This type of encapsulation is related with the use of virtual tunnels between VMs. Actually there are several ways to make these tunnels:

- IP over IP Tunneling
- General Routing Encapsulation (GRE) Tunneling
- OpenVPN Tunneling

Fig. 15 - IP over IP encapsulation diagram [12]

IP to over IP is a data encapsulation method, in which the Payload data is masked within two IP headers; specifically, an IP header is added to the original IP header being able to encapsulate the data and thus transport it through multiple networks without affecting the traffic between the communicated endpoints. Since this transport protocol works on level 3 of the TCP/IP protocol stack, it does not fulfill the requirements to security configuration of CCP Amazon EC2. Therefore, this encapsulation protocol is not allowed to pass through this platform, which prevents its function.

Fig. 16 - GRE encapsulation diagram [13]

GRE is an encapsulation protocol that does the same function of IP over IP, since this protocol transport the payload through several network nodes. However, this protocol

uses a different header than the IP over IP protocol and it encapsulates the data using a header that operates on the same layer as the TCP, UDP and ICMP; that means that this protocol would be prevented to function in the Amazon EC2 platform.

The two first alternatives require the use of transport protocols different from TCP/UDP, which is the reason why they are automatically discarded. This is due to the limitations in the communication between VMs imposed by the CCP Amazon EC2.

The other alternative is OpenVPN, which is a tool for site to site interconnection based in the implementation of protocol TLS/SSL as well as pre-shared keys. The operation of OpenVPN is done over the transport layer of the TCP/IP protocol stack, which means that this tool could manage encapsulation process through the TCP/UDP protocols. With this tool it could create several tunnels to interconnect different endpoints in the CCP Amazon EC2.

6.5 Solution Development

For the development of the OpenVPN based solution a virtual laboratory with two Vyatta virtual routers was created. By using these routers it was able to verify the viability of the OpenVPN solution.

Deploy Job: Vyatta Tunneling Lab

Basic Information

Job Run Name: Enter a name for the Job Run.

Description: Enter the description.

User Notes: Enter any notes for the user. You may enter HTML.

Job Deployment Lease Time: DEFAULT Default Timeout [3 Hour(s)] Job will be automatically undeployed if it is active for longer than the specified lease time. Note: Entering '0' would mean 'No Timeout'.

[Advanced Options](#)

Fig. 17 - VMLogix Vyatta Lab 1

Machine Role: Router1

Select Machine Template: Choose the Machine Template to install for this role. You can also request a machine with specific amount of RAM and other options.

Deploy On Machine: You can specify a specific machine or a labeled group of machines to run this role on.

Machine Role: Router2

Select Machine Template: Choose the Machine Template to install for this role. You can also request a machine with specific amount of RAM and other options.

Deploy On Machine: You can specify a specific machine or a labeled group of machines to run this role on.

Fig. 18 - Vyatta Lab 1 – OS selection

Role: Router1	
	Technology:
	Host:
	Public DNS :
	Private DNS:
Router1	Amazon EC2 EC2-Host [1960-6476-2155@US-East] ec2-75-101-215-63.compute-1.amazonaws.com ip-10-243-119-131.ec2.internal
Role: Router2	
	Technology:
	Host:
	Public DNS :
	Private DNS:
Router2	Amazon EC2 EC2-Host [1960-6476-2155@US-East] ec2-174-129-75-216.compute-1.amazonaws.com ip-10-243-118-224.ec2.internal

Fig. 19 - Lab 1 Deployed Configuration

In this step, the testing VMs were using pre-shared keys as the way to simplify the use of OpenVPN. With this key there was able to establish a communication link. This is the

simplest way to connect, since only one shared key for both routers is needed to be created.

```
root@ec2-75-101-215-63.compute-1.amazonaws.com's password:
Linux vyatta 2.6.27-19-xen #1 SMP Tue Jan 20 15:59:22 UTC 2009 i686
Welcome to Vyatta.
This system is open-source software. The exact distribution terms for
each module comprising the full system are described in the individual
files in /usr/share/doc/*/copyright.
Last login: Sun Apr  4 03:21:15 2010 from 64.32.91.248
vyatta:~# openvpn --genkey --secret /root/secret
vyatta:~#
```

Fig. 20 - Pre-shared key generation

The first step consists in the creation of the shared-key. Using the “openvpn –genkey –secret” console command it was created the key that will be used to establish the link between both routers.

After that there was needed to copy that key in the other router, and for that there was used the SCP command:

```
vyatta:~# scp /root/secret root@ip-10-243-118-224.ec2.internal:/root/.
root@ip-10-243-118-224.ec2.internal's password:
secret                                     100% 636      0.6KB/s   00:00
vyatta:~#
```

Fig. 21 - Key sharing

Then, the OpenVPN tunnel configuration was continued in router #1:

```
vyatta:~# configure
[edit]
root@vyatta# set interfaces openvpn vtun0
[edit]
root@vyatta# set interfaces openvpn vtun0 local-address 192.168.100.1
[edit]
root@vyatta# set interfaces openvpn vtun0 mode site-to-site
[edit]
root@vyatta# set interfaces openvpn vtun0 remote-address 192.168.100.2
[edit]
root@vyatta# set interfaces openvpn vtun0 remote-host ip-10-243-118-224.ec2.inte
rnal
[edit]
root@vyatta# set interfaces openvpn vtun0 shared-secret-key-file /root/secret
[edit]
root@vyatta# commit
[edit]
root@vyatta#
```

Fig. 22 - Router #1 Configuration

After that, the same procedure was performed with the second router, and to proof the concept Loopback interfaces were added. In the same way, static routes were added to reach the second router's IP segment, and vice versa.

```
root@vyatta# set interfaces loopback lo address 192.168.102.1/24
[edit]
root@vyatta# set protocols static route
route route6
[edit]
root@vyatta# set protocols static route 192.168.101.0/24 next-hop 192.168.100.2
[edit]
```

Fig. 23 - Loopback interface configuration

For the scheme verification, a connectivity test was performed between both routers:

```
root@vyatta# ping 192.168.101.1
PING 192.168.101.1 (192.168.101.1) 56(84) bytes of data.

6.6 Final Test

Fig. 26 - Final Test's configuration

For the implementation of the final test it was using a four VMs configuration, which was including two Vyatta routers, and two Windows 2003 as endpoints. Within this configuration it was using pre-shared keys and the TLS/SSL protocol to interconnect the Windows VM with each router.

Job #2119: Vyatta Tunneling Lab2

The screenshot shows the 'Job #2119: Vyatta Tunneling Lab2' configuration page. At the top, there is a row of icons for 'All Roles' (a stack of monitors) and four VMs: 'TestMachine1', 'Router1', 'Router2', and 'TestMachine2'. Below this is a tabbed interface with 'Job Details', 'All Consoles', and 'Job Networking'. The 'Job Details' tab is active, showing 'Job Information' with the following details:

Name:	Vyatta Tunneling Lab2
Id:	2119
Description:	2 Routers + 2 Endpoint Machines
User Notes:	
Status:	 Active
Duration:	 < 1 min
Job Deployment Lease Time:	12 hrs left (out of 12 hrs of Lease)
 Advanced Options	

Fig. 27 - Final Test Deployed configuration

The TLS/SSL requires the creation of several security certificates that are used on the client-server transaction, therefore there are some steps that are needed in order to begin

the creation of the certificates, and these steps can be found on the main page of OpenVPN organization [14].

7 Results and Conclusion

The Thesis has successfully completed a networking laboratory scheme. The results of this Thesis could be extracted from the test environment section. Within this Thesis the CCP Amazon EC2 was analyzed and there was found that this platform presents several limitations that do not allow users to construct network laboratories without the use of other tools. The main goal of this Thesis was to develop a solution that includes the configuration of the VMs, analysis of the accessible tools in the market, and the use of those tools to be capable to develop a networking laboratory scheme.

The first configuration scheme was based on the use of two Vyatta routers as proof of concept for the development of the laboratory. With this configuration we pursued to test the OpenVPN solution to determine if we were going to be able to interconnect those routers. For the second configuration, it was used an expansion of the first configuration with the inclusion of two end points. Also, a dynamic routing protocol (RIP) was used to test the routing capabilities of this solution. This configuration included the authentication of the Windows clients with SSL certificates.

With the use of OpenVPN, as well as the TLS/SSL protocols, the solution was able to interconnect through a series of tunnels, two endpoints (Windows VMs). Furthermore, by using static and dynamic protocols it was able to exchange routing information between two Vyatta Routers. Although, the use of OpenVPN+Tunneling increased the difficulty of the laboratory scheme, this solution could be reduced in complexity with the use of pre-made configurations, where the VM might be configured already to begin with this

implementation easily.

Finally the CCP Amazon EC2 could be used with the help of VMLogix and OpenVPN to develop several network configuration schemes, which could help create a successful educational platform in the Networking area.

8 Future work

The objective of this Thesis was to develop a virtual networking laboratory with the use of the CCP Amazon EC2. During the Thesis development several obstacles were encountered that made complex the process to complete this task. The final solution involved the use of OpenVPN tunneling which increase the time and the complexity of the laboratory. This Laboratory would be difficult to build by students; therefore, it would be helpful to improve the construction way of this laboratory by using predefined VM images to reduce the complexity and made easy the development for the final user. Also, the complexity could be reduced by the use of the VMLogix scripting options. Another future work related to this Thesis would be the use of dynamic routing protocols different from RIP.

On the other hand, by the time of this Thesis development, Amazon introduced -in beta format on one data center- its new cloud computing product named Amazon Virtual Private Cloud (Amazon VPC), which is based on the Amazon EC2 platform. This software introduces the use of the customer's isolated AWS resources, in which the owner of the private cloud could assign its own private subnets, as well as a VPN tunnel to the private user's facilities.

Fig. 40 - Amazon Virtual Private Cloud (VPC)

The Amazon VPC could be used in conjunction of VMLogix to develop a Virtual Laboratory, which could be designed to be accessed only for the authorized campus connections. It would be useful to use private subnets with the VMLogix, because the networking laboratories would be developed easily. Actually VMLogix does not offer the required options to control the IP subnet assignment of the virtual configurations. The VMLogix Lab Manager needs to be redesigned to allow the VPC features to work in this tool.
